

BKC WEATHERSYS · DATA GUIDE

Where Your Dashboard's Data Comes From

A plain-language walkthrough of the WeatherOps dashboard: which screens are live today, where their numbers actually come from, and what would need to change to switch over to your organization's real weather system.

The short version

Every screen on the dashboard works and looks complete today, but the weather numbers behind almost all of them are **practice data** — realistic numbers invented by the app itself, not readings from a real sensor or a real database. The only genuinely real things in the app right now are the **list of tower sites/circles** and the **login system**. Everything else is a stand-in, built so the dashboard could be designed and tested before it's wired up to your actual weather system.

The dashboard has one central data hub. Today, only the amber path (the built-in practice data generator) is actually turned on; the grey dashed path (your real weather system) is ready to be connected but nothing is plugged into it yet.

Screen by screen: what's behind each one

This table lists every major area of the dashboard, what it shows you, and exactly where that information comes from right now versus where it would come from once connected to a real system.

Dashboard area	Where the data comes from today	Where it would come from, once connected
Live Map & current conditions	Invented on the spot by the app's practice data generator	Your live sensor/API feed, refreshed continuously
Forecasts (7-day & hourly slider)	Same practice generator, projected forward in time	Your forecasting system or meteorological data provider
Historical weather & comparisons	Practice generator, built to look like a believable history	Your archived/historical weather records
Alerts & hazard warnings	Calculated from the practice weather numbers above	Calculated the same way, but from your real weather feed
Daily bulletins & PDF reports	Assembled from whichever practice numbers each report covers	Same reports, built from real figures once connected
Cyclone tracker	One fixed, hand-set demo storm - see note below	Would need a dedicated cyclone data feed to be built - none exists today, mock or real
Tower sites & circle names	Real. The actual list of your sites, states and circles	No change needed - already real
User login	Real & working, using a temporary practice database	Same login system, pointed at your permanent database

A closer look: the cyclone tracker

The cyclone tracker works differently from everything else in the app, and it's worth calling out on its own. It is not connected to the practice data generator, and it is not connected to anything else either. It shows one single storm track that was manually set once, and every user of the dashboard sees that exact same storm, all the time - it never updates and does not represent a real, current cyclone.

The one exception: cyclone tracking

If real cyclone tracking is needed, it would have to be built from scratch as a new connection - unlike the rest of the app, there isn't even a practice-data version of it feeding a real structure that a live feed could later slot into.

What it would take to switch to real data

Turning on the grey "real weather system" path in the diagram above is mainly a matter of information, not a rebuild - the dashboard was designed to accept a real data source in place of the practice generator, feature by feature. To move forward, we'd need from your team:

- 1 The web address (URL) of your weather system**
So the dashboard knows where to ask for data.
- 2 A sample of what your system sends back**
So the dashboard's screens can be matched up to your system's real fields and units.

3 How to sign in to it

The dashboard already expects a standard secure login step (a token from a login page) - we'd confirm your system works the same way.

Once that information is available, each screen can be switched over one at a time - the dashboard doesn't need to go all-or-nothing, and everything keeps working on practice data in the meantime for anything not yet connected.
